More than one-quarter of women with a hip fracture will be dead within 12 months; maintaining and protecting bone health postmenopause is paramount. In this article: WHI findings on hip fracture, treatment-level fracture scores in women older and younger than age 65, and updated USPSTF recommendations for screening.

As ObGyns, we are the first-line health care providers for our menopausal patients in terms of identifying, preventing, and initiating treatment for women at risk for fragility fractures. Osteoporosis is probably the most important risk factor for bone health, although sarcopenia, frailty, poor eyesight, and falls also play a significant role in bone health and fragility fracture.

In 2005, more than 2 million incident fractures were reported in the United States, with a total cost of $17 billion.1 By 2025, annual fractures and costs are expected to rise by almost 50%. People who are 65 to 74 years of age will likely experience the largest increase in fracture—greater than 87%.1

Findings from the Women’s Health Initiative study showed that the number of women who had a clinical fracture in 1 year exceeded all the cases of myocardial infarction, stroke, and breast cancer combined.2 Furthermore, the morbidity and mortality rates for fractures are staggering. Thirty percent of women with a hip fracture will be dead within 1 year.3 So, although many patients fear developing breast cancer, and cardiovascular disease remains the number 1 cause of death, the impact of maintaining and protecting bone health cannot be emphasized enough.

**WHI incidental findings:**
Hormone-treated menopausal women had decreased hip fracture rate

US multiethnic postmenopausal women aged 50 to 79 years (mean age at baseline, 63.4 years) enrolled in 2 randomized clinical trials between 1993 and 1998 and followed up through December 31, 2014. A total of 27,347 women were randomly assigned to treatment.

**Treatment groups**

Depending on the presence or absence of a uterus, women received conjugated equine estrogens (CEE, 0.625 mg/d) plus medroxyprogesterone acetate (MPA, 2.5 mg/d) (n = 8,506) or placebo (n = 8,102) for a median of 5.6 years or CEE alone (n = 5,310) versus placebo (n = 5,429) for a median of 7.2 years. All-cause mortality (the primary outcome) and cause-specific mortality (cardiovascular disease mortality, cancer mortality, and other major causes of mortality) were analyzed in the 2 trials pooled and in each trial individually.

**All-cause and cause-specific mortality findings**

Mortality follow-up was available for more than 98% of participants. During the cumulative 18-year follow-up, 7,489 deaths occurred. In the overall pooled cohort, all-cause mortality in the hormone therapy group was 27.1% compared with 27.6% in the placebo group (hazard ratio [HR], 0.99 [95% confidence interval (CI), 0.94–1.03]). In the CEE plus MPA group, the HR was 1.02 (95% CI, 0.96–1.08). For those in the CEE-alone group, the HR was 0.94 (95% CI, 0.88–1.01).

In the pooled cohort for cardiovascular mortality, the HR was 1.00 (95% CI, 0.92–1.08 [8.9% with hormone therapy vs 9.0% with placebo]). For total cancer mortality, the HR was 1.03 (95% CI, 0.95–1.12 [8.2% with hormone therapy vs 8.0% with placebo]). For other causes, the HR was 0.95 (95% CI, 0.88–1.02 [10.0% with hormone therapy vs 10.7% with placebo]). Results did not differ significantly between trials.

**FAST TRACK**

The 2017 WHI investigators observed 27,347 women aged 50 to 79 years who were treated with hormone therapy or placebo and followed for a median of 5.6 years (CEE plus MPA) or 7.2 years (CEE alone).
In a study of 4,957 women ≥67 years with normal BMD or osteopenia, the estimated time for 10% of women to transition to osteoporosis was 16.8 years for those with normal BMD, 4.7 years for those with moderate osteopenia, and 1.1 years for women with advanced osteopenia.

M any clinicians used to (and still do) order bone mineral density (BMD) testing at 23-month intervals because that was what insurance would allow. Gourlay and colleagues previously published a study on BMD testing intervals and the time it takes to develop osteoporosis. I covered that information in previous Updates.4,5

To recap, Gourlay and colleagues studied 4,957 women, 67 years of age or older, with normal BMD or osteopenia and with no history of hip or clinical vertebral fracture or of treatment for osteoporosis; the women were followed prospectively for up to 15 years. The estimated time for 10% of women to make the transition to osteoporosis was 16.8 years for those with normal BMD, 4.7 years for those with moderate osteopenia, and 1.1 years for women with advanced osteopenia.

**Key takeaway**
The study authors concluded that among postmenopausal women, hormone therapy with CEE plus MPA for a median of 5.6 years or with CEE alone for a median of 7.2 years was not associated with risk of all-cause, cardiovascular, or cancer mortality during a cumulative follow-up of 18 years.

**Appropriate to defer DXA testing to age 65 when baseline FRAX score is below treatment level**

Today, FRAX is recommended to assess need for treatment.

Older treatment recommendations involved determining various osteopenic BMD levels and the presence or absence of certain risk factors. More recently, the National Osteoporosis Foundation and many medical societies, including the American College of Obstetricians and Gynecologists, have recommended using the FRAX fracture prediction algorithm (available at https://www.shef.ac.uk/FRAX) instead of T-scores to consider initiating pharmacotherapy.

The FRAX calculation tool uses information such as the country where the patient lives, age, sex, height, weight, history of previous fracture, parental fracture, current smoking, glucocorticoid use, rheumatoid arthritis, secondary osteoporosis, alcohol use of 3 or more units per day, and, if available,
Providers and their patients should be aware that if the fracture risk is beneath the BMD threshold score at baseline, the risk of experiencing an osteoporotic fracture prior to age 65 is extremely low, and this should be taken into account before prescribing pharmacotherapy. Furthermore, as stated, FRAX can be performed without a DXA score. When the result is beneath a treatment level in a woman under 65, DXA testing may be deferred until age 65.

**WHAT THIS EVIDENCE MEANS FOR PRACTICE**

Many health care providers begin BMD testing early in menopause. Bone mass results may motivate patients to initiate healthy lifestyle choices, such as adequate dietary calcium, vitamin D supplementation, exercise, moderate alcohol use, smoking cessation, and fall prevention strategies. However, providers and their patients should be aware that if the fracture risk is beneath the threshold score at baseline, the risk of experiencing an osteoporotic fracture prior to age 65 is extremely low, and this should be taken into account before prescribing pharmacotherapy. Furthermore, as stated, FRAX can be performed without a DXA score. When the result is beneath a treatment level in a woman under 65, DXA testing may be deferred until age 65.

**USPSTF offers updated recommendations for osteoporosis screening**

The 2018 updated osteoporosis screening recommendations from the United States Preventative Services Task Force (USPSTF) may seem contradictory to the conclusions of Gourlay and colleagues discussed above. They are not.
Evidence on bone measurement tests, risk assessment tools, and drug therapy efficacy

The USPSTF conducted an evidence review on screening for and treatment of osteoporotic fractures in women as well as risk assessment tools. The task force found the evidence convincing that bone measurement tests are accurate for detecting osteoporosis and predicting osteoporotic fractures. In addition, there is adequate evidence that clinical risk assessment tools are moderately accurate in identifying risk of osteoporosis and osteoporotic fractures. Furthermore, there is convincing evidence that drug therapies reduce subsequent fracture rates in postmenopausal women.

The USPSTF recommends the following:
- For women aged 65 and older, screen for osteoporosis with bone measurement testing to prevent osteoporotic fractures.
- For women younger than 65 who are at increased risk for osteoporosis based on formal clinical risk assessment tools, screen for osteoporosis with bone measurement testing to prevent osteoporotic fractures.

WHAT THIS EVIDENCE MEANS FOR PRACTICE

We all agree that women older than 65 years of age should be screened with DXA measurements of bone mass. The USPSTF says that in women under 65, a fracture assessment tool like FRAX, which does not require bone density testing to yield an individual’s absolute 10-year fracture risk, should be used to determine if bone mass measurement by DXA is, in fact, warranted. This recommendation is further supported by the article by Gourlay and colleagues, in which women aged 50 to 64 with subthreshold FRAX scores had a very low risk of fracture prior to age 65.
