USP Asks for Help in Headling Off Drug Errors

BY BRUCE K. DIXON
Chicago Bureau

The soaring numbers of commonly used drugs with soundalike and look-alike names have prompted the U.S. Pharmacopeia to ask physicians and pharmacists to include an “indication for use” on prescriptions.

This and other recommendations are contained in U.S. Pharmacopeia’s 8th annual MEDMARX report, which is based on a review of more than 26,000 records submitted to the MEDMARX database from 2003 to 2006.

The records implicate nearly 1,500 drugs in medication errors due to brand or generic names that could be confused. From these data, U.S. Pharmacopeia (USP) compiled a list of more than 3,000 drug pairs that look or sound alike, a figure that is nearly double the number of pairs identified in USP’s 2004 report, said Diane Cousins, R.Ph. “We were surprised to see that much of an increase in such a short time, and the concern is that this increase in products in the marketplace further raises the opportunity for error,” said Ms. Cousins, USP’s vice president of health care quality and information.

USP also reported, in conjunction with the Institute for Safe Medication Practices, the Medication Errors Reporting Program (MER), which allows providers to confidentially report potential and actual medication errors directly to USP.

USP reviewed both MEDMARX and MER to summarize the variables associated with more than 26,000 look alike and/or soundalike (LASA) errors, of which 1.4% (384) resulted in harm or death. More than 670 health care facilities contributed 26,000 records, according to the 400-page report.

“We looked at lists of the top 200 drugs prescribed and used in hospitals, and virtually every time, all of the top 10 appeared within the USP similar names list,” Ms. Cousins said in an interview.

An important finding of this year’s report is the role of pharmacy staff in LASA-related errors, she said. “Although pharmacy personnel, who are generally technicians, may enter an indication for use” on prescriptions, it is as a group identified, prevented, and reported more than any other staff.”

The report also identifies an emerging trend of look-alike drug names in computerized direct order entry systems as a source of confusion. “This trend will likely continue as these systems become a standard of practice,” she said, adding that the LASA related error problem is further compounded by the indiscriminate use of suffixes, as well as the look-alike packaging and labeling.

Over the 3-year period, the drug most commonly confused with others was Ce- fazolin, a first-generation cephalosporin antibiotic. “We found it to be confused with 15 other drugs, primarily antimicrobials, which might be explained by the fact that this is the most frequently used class of drugs,” said Ms. Cousins.

Among other major paired LASAs were cardiovascular drugs, such as lisinopril and enalapril, and central nervous system agents, like trazodone and chlorpromazine.

Drug mix-ups led to seven reported fatalities, including two deaths attributed to confusion over the Alzheimer’s drug Reminyl (galantamine) and the antidepressant drug bupropion (Wellbutrin). In 2005, recognizing the high risk of confusion and subsequent fatal hyponglycemia, Ortho-McNeil Neurologics Inc. announced the name Reminyl had been changed to Razadyne to avoid confusion with Amaryl.

In another case, an autistic pediatric patient was given the wrong product when disodium EDTA (a hyperalimentation treatment) was administered instead of the chemotherapy agent calcium disodium EDTA, which is approved by the Food and Drug Administration for the treatment of lead poisoning and was prescribed in an attempt to help treat the patient’s autism.

In each case, an emergency department physician was preparing to intubate a patient and calculated the right dose of zemuron (Zemuron), a preintubation agent. The physician gave orders for the nurse to obtain the medication and indicated the volume to be administered, Ms. Cousins said. “The nurse obtained and administered the neuromuscular blocking agent vecuronium (Norcuron) instead. The patient received a large amount of the wrong agent, which led to a fatal heart arrhythmia.”

The remaining three reported deaths involved mix-ups between the anticonvulsant primidone and prednisone; the antipsychotic drug haloperidol and the barbiturate phenobarbital; and Norcuron and the heart failure treatment Na-trecor (nesiritide reconstituant).

Errors occur with over-the-counter medications, too. Ms. Cousins described the mortal confusion when an order for Furo-sequel 500 mg—an iron replacement—was transcribed as Serquequel 500 mg and the order read as Seroquel 500 mg—an antipsychotic.

The rate of mix-ups involving brand name versus generic drugs was about evenly split, 57% and 43%, respectively. Ms. Cousins said, adding that while most errors were made in pharmacies, many such as the primidone-prednisone incident, are due to confusion over the prescribing physician’s handwriting, which lead the pharmacist to issue the wrong drug.

“Errors also are due to physicians using short codes for medications, such as ‘clon,’ for clonazepam or clonopine,” she said, adding that electronically written prescriptions using a computer or label machine would eliminate many errors. “Anything that takes handwriting out of the equation is a help. It would also be helpful if the FDA were given more authority to force name changes during the drug review process, as has been suggested by the Institute of Medicine. It is much more difficult to correct a name confusion issue once the products are on the market.”

The recommendation that physicians in- clude a description of the prescription is not an attempt by USP to impose on privacy, Ms. Cousins said. “All that is needed are simple inclusions, such as ‘for si- nous,’ ‘for heart,’ or ‘for cough,’” she said. “USP also recommends that ‘full man lettering’ be implemented in pharmacy software, labeling, and order writing; for example, ‘acetaZOLamide’ (glaucoma) vs. ‘acetazolamide’ and ‘curonium’ (Norcuron) vs. ‘curonium (Norcuron).’

Where risk exists, take action to reduce the chance for error. To build awareness, USP recommends disseminating information about products that have been confused at your facility, and prohibiting verbal orders for soundalikes.

“Physicians’ offices should always require a read-back from pharmacists, making sure that they both read and spell the drug name,” Ms. Cousins said.

Some errors result from physicians’ use of the same abbreviation for two drugs: clon for clonazepam and clonopine.

U.S. Spent $2 Trillion on Health Care in 2006, Drug Tab Up 8.5%

BY ALICIA AULT
Associate Editor, Practice Trends

WASHINGTON — The nation spent $2 trillion, or $7,000 per person, on health care in 2006. While that was only a small increase from the previous year, America’s prescription drug tab increased by 8.5%.

Health spending as a share of the nation’s gross domestic product hit 16% in 2006.

Total spending on physician and clinical services grew 5.9% to $448 billion, which was the slowest rate of growth since 1999. Physician pay crawled almost to a halt, largely because of the freeze in Medicare payments for physicians in 2006. Private insurers seemed to have followed suit, said Cathy Cowan, an economist at the Cen- ter for Practice Use on prescription Medicad Services. Cowan, a coauthor of an annual analysis of the nation’s health spending, spoke at a brief-
