Extra Vitamin D Fails to Cut Fibromyalgia Pain

BY TIMOTHY F. KIERN
San Diego — Vitamin D supplementation did not lessen fibromyalgia symptoms in a small trial, a finding that casts doubt on the theory that vitamin D deficiency underlies some patients' pain and that vitamin D levels would identify patients who would benefit from supplementation, Dr. Ann Warren said in a poster presentation at the annual meeting of the American College of Rheumatology.

She performed two studies examining the vitamin D hypothesis. In one study, Dr. Warren, a rheumatologist who practices in Honolulu, Mo., took 36 women with fibromyalgia on placebo for 3 months, then randomized them to 50,000 IU of vitamin D or to placebo for 3 months.

The 25 patients who were randomized to supplementation had a higher mean pain score on a visual analog scale at baseline compared with the patients who received placebo (74 mm vs. 61 mm). The mean pain score of patients given supplements after 3 months, falling to 64 mm.

However, the mean visual analog scale score of the control patients fell to a similar degree, to 54 mm, and neither group's changes were statistically significant.

Patients in the control group showed a slight, but significant improvement on the functional pain score, while the supplemented group did not.

In the second study, Dr. Warren compared 25-hydroxyvitamin D levels in 104 women with osteoarthritis with levels in 184 fibromyalgia patients.

There was no statistically significant difference in mean levels between the groups —72 ng/ml for the arthritits group versus 29.16 for the fibromyalgia group— even though there was a slightly higher percentage of patients with fibromyalgia who were insufficient, 29% vs. 20%.

In an interview, Dr. Warren said the vitamin D hypothesis achieved some credibility in 2003 when an article in the Mayo Clinic Proceedings reported that 93% of a group of 150 patients with diffuse musculoskeletal pain were vitamin D insufficient.

The article was accompanied by an editorial suggesting that vitamin D deficiency was so common that all patients with diffuse pain should perhaps have their levels checked.

The therapy, however, to make sense, since vitamin D deficiency causes osteomalacia.

Her studies had some possibly confounding features, Dr. Warren said. In the supplementation study, even the control patients had an improvement in their vitamin D levels during the course of the study because the weather turned warmer. And in the second study, the osteoarthritis patients were significantly older (an average of 60 years versus 54 years).

Still, neither group in the first study had a significant change in their visual analog scale pain scores, and age did not correlate statistically with vitamin D level in the second study.

“While we would not need to be checking vitamin D levels in patients with fibromyalgia,” Dr. Warren said.

Shedding Weight Aids Fibromyalgia Pain

Behavioral weight loss treatment benefited overweight and obese women with fibromyalgia syndrome, reported Jennifer R. Shapiro, Ph.D., and her colleagues at the University of Albany, State University of New York.

In a 20-week pilot study, 31 overweight or obese Caucasian women with fibromyalgia syndrome lost an average of 9.2 lbs, or more than 4% of their initial body weight. Most who lost weight shed at least 5% of their initial body weight (J. Psychosomatic Res. 2005;59:273-82).

The intervention entailed small group meetings every week for 1.5 hours, along with use of guidelines for diet and exercise.

Weight loss treatment at week 20 was significantly associated with improvements in anxiety, pain, and sleep concerns, support, and quality of life, the investigators said. “The amount of weight loss, as opposed to both absolute weight and treatment participation, is the better predictor of pain improvement,” the researchers said.
