Glycerol Effective for Children’s Bacterial Meningitis

BY MITCHEL L. ZOLER
Philadelphia Bureau

WASHINGTON — Adjunctive treatment with oral glycerol was more effective than intravenous dexamethasone for preventing death and severe neurologic sequelae in children with bacterial meningitis in a controlled study with 640 patients.

“Because oral glycerol is safe, cheap, and easily available and does not have special storage requirements, it seems to be the best approach for improving the outcome of bacterial meningitis in children,” Heikki Peltola, M.D., said at the annual Interscience Conference on Antimicrobial Agents and Chemotherapy.

Although dexamethasone is often used as an adjunctive treatment for children with bacterial meningitis, its efficacy has never been proven. Several physicians have hypothesized that glycerol would be an effective adjunctive agent because of its activity as a free-radical scavenger.

To test both agents, a study was done in the pediatric departments of 10 universities in South America and Helsinki, Finland.

The study was supported by a grant from GlaxoSmithKline, but the study’s design, conduct, and analysis were independent of commercial influence, said Dr. Peltola, a professor of infectious diseases at the Hospital for Children and Adolescents at Helsinki University Central Hospital.

Children aged 2 months or older with bacterial meningitis were all treated with ceftriaxone. They were also randomized to one of four adjunctive treatment groups: dexamethasone only, glycerol only, both dexamethasone and glycerol, or placebo. About 160 patients were randomized to each treatment group.

Patients treated with glycerol received a dosage of 6.0 g/kg daily, given orally in four divided doses. Patients who received dexamethasone were given a dosage of 1.0 mg/kg intravenously every 6 hours.

Results

Of 1,108 cases in the database, complete data were retrieved for 754 patients, of whom 58 were excluded either because their infection was nosocomial, they had had recent neurosurgery, or they had received a neurosurgical device.

In a review of 696 patients with community-acquired, acute bacterial meningitis, the classic symptom triad occurred in only 44% of the patients, Dr. van de Beek reported in his poster. (The data have been published: N. Engl. J. Med. 2004;351:1849-59).

Of the 696 patients, 21% died and 13% had other unfavorable outcomes including a vegetative state or severe or moderate disability. The likelihood that a patient would have an unfavorable outcome was sixfold higher among patients who were infected with *Streptococcus pneumoniae* than among those infected with *Neisseria meningitides* when the incidence rates were adjusted for potential clinical confounders.

This study is the first report of a prospective, large-scale analysis of the clinical factors associated with bacterial meningitis and its outcomes, Dr. van de Beek said at the conference, sponsored by the American Society for Microbiology.

The study data were drawn from information on all patients who were at least 16 years old and diagnosed with bacterial meningitis in the Netherlands Reference Laboratory database from October 1998 through April 2002.

Most Don’t Present With Meningitis Triad

WASHINGTON — Less than half of patients with bacterial meningitis have the classic symptom triad of fever, stiff neck, and a change in mental status, Diederick van de Beek, M.D., said while presenting a poster at the annual Interscience Conference on Antimicrobial Agents and Chemotherapy.

Many patients present with just two classic symptoms, one of which may also be headache, said Dr. van de Beek, a neurologist at the Academic Medical Center in Amsterdam.

In a review of 696 patients with community-acquired, acute bacterial meningitis, the classic symptom triad occurred in only 44% of the patients, Dr. van de Beek reported in his poster. (The data have been published: N. Engl. J. Med. 2004;351:1849-59).

In contrast, 95% of patients had at least two classic symptoms. The most common classic symptom was headache in 87%, followed by neck stiffness in 83%, fever in 77%, and a change in mental status in 69% (defined as a Glasgow Coma Scale score of less than 14).

Of the 696 patients, 21% died and 13% had other unfavorable outcomes including a vegetative state or severe or moderate disability. The likelihood that a patient would have an unfavorable outcome was sixfold higher among patients who were infected with *Streptococcus pneumoniae* than among those infected with *Neisseria meningitides* when the incidence rates were adjusted for potential clinical confounders.

This study is the first report of a prospective, large-scale analysis of the clinical factors associated with bacterial meningitis and its outcomes, Dr. van de Beek said at the conference, sponsored by the American Society for Microbiology.

Of 1,108 cases in the database, complete data were retrieved for 754 patients, of whom 58 were excluded either because their infection was nosocomial, they had had recent neurosurgery, or they had received a neurosurgical device.

Rethinking Influenza Vaccination

Helping to Stimulate the Natural Defense Pathways

Patients count on an effective vaccine

Many people have come to rely on influenza vaccines—parents of young children, people at high risk for influenza-related complications, healthcare workers, and healthy people who simply want to avoid getting the flu.

Influenza vaccines are prepared in advance of the season and comprise the 3 strains predicted by the US Public Health Service and the World Health Organization to be most prevalent in the coming season. The vaccine is available as either a nasally administered, attenuated, live cold-adapted influenza vaccine (CAIV), or as injectable trivalent influenza vaccines that contain inactivated virus.
