Nodular melanoma, unlike superficial spreading melanoma, is typically located on the head and neck or distal limbs, and small lesion that has a high Breslow thickness, which are common forms of the disease, such as superficial spreading melanoma.

But these criteria do not apply to nodular melanomas, which typically are round, elevated, red or pink, and uniform in color or throughout. They also carry a poor prognosis because they are likely to be deeper when identified—and lesion depth correlates with outcome.

A review of all 3,353 reported cases was done on covered sites of the body.

Urban Skin: Susceptible to sun exposure and treated with NMDA receptor antagonists.

Memantine is predominantly renally eliminated, and drugs that are strong inhibitors of renal tubular secretion could potentially result in altered plasma levels of both agents. However, there have been no studies of concomitant use of NMDA receptor antagonists with other NMDA receptor antagonists. Therefore, caution should be exercised when administering memantine concomitantly with other NMDA receptor antagonists.
