Nonalcoholic Fatty Liver Emerging As Major Health Burden in the U.S.

BY MIRIAM E. TUCKER

Philadelphia — Nonalcoholic fatty liver disease (NAFLD) is defined as a major health burden in the United States, Dr. Rajender Reddy said at the annual meeting of the American College of Physicians. Daily association with obesity and underlying insulin resistance, nonalcoholic fatty liver disease (NAFLD) is believed to affect as many as 20%–30% of the U.S. population, said Dr. Reddy, professor of medicine and surgery and director of hepatology at the University of Pennsylvania, Philadelphia.

There is some debate about the amount of alcohol ingestion permitted to make the distinction between alcoholic hepatitis and NAFLD, which is defined as increased liver weight by 5%–10% from fat accumulation (steatosis), in the absence of excessive alcohol consumption. Most experts agree, however, that overall alcohol consumption of less than 20 g per day is well below what would be associated with significant alcoholic liver disease, noted Dr. Reddy, who is also medical director of liver transplantation at the University of Pennsylvania.

Classification of NAFLD falls into four types: Type 1 (fatty liver alone) and type 2 (fat accumulation and lobular inflammation) are considered to be NAFLD alone. The more serious types 3 (fat accumulation and ballooning degeneration) and 4 (fat accumulation, ballooning degeneration, and either Mallory hyaline and/or fibrosis) are characterized as nonalcoholic steatohepatitis (NASH).

There is a tendency to use the term NASH loosely in everyone who has nonalcoholic fatty liver disease. You should use the general term NAFLD and reserve NASH only for those who have histologic evidence of steatohepatitis,” Dr. Reddy advised.

Overall, about 10% of patients with NAFLD and 1%–4% with NASH limit data on the natural history of these conditions suggest that about 15%–20% of patients with steatosis will progress to steatohepatitis at some point. Of those, smaller numbers will go on to develop fibrosis, cirrhosis, and hepatocellular carcinoma.

Factors that predict progression from NAFLD to NASH include age greater than 45 years, type 2 diabetes, body mass index greater than 35 kg/m², hypertension, and liver enzyme abnormalities. Overall, the 1- and 5-year survival rate for NASH have been reported to be 67% and 59%, respectively. But the mortality is not always liver-related and could be due to comorbid conditions such as hypertension, dyslipidemia, and diabetes. In one recent study of 420 NAFLD patients in Minnesota who were followed for a mean of 7.6 years, mortality was 34% greater than expected for the general Minnesota population (Gastroenterology 2005;129:113-21). Data pertaining to treatment of NAFLD are also limited, but weight management is considered a priority for patients because of proven benefits in cardiovascular risk profile. Small anecdotal studies have indicated an improvement in biochemical parameters and liver histology with exercise and/or diet, which weight reduction of 10%–15% more has been shown to correct amiotransferase abnormalities and decrease hepatomegaly.

Age Should Not Hinder Gastric Bypass Candidacy

BY MARY ELLEN SCHNEIDER

Los Angeles — Both seniors and adolescents can be good candidates for Roux-en-Y gastric bypass surgery, according to new research presented at the annual Digestive Disease Week.

In a review of 167 surgical cases at the Mayo Clinic in Rochester, Minn., involving patients aged 60 or older and adolescents aged 12-18 years, researchers found a significant decrease in obesity-related mortality after gastric bypass surgery, and limited morbidity and mortality overall.

The researchers reviewed the Mayo Clinic’s 20-year bariatric surgery database and obtained morbidity and mortality rates from medical records. They also sent a questionnaire to surviving patients.

The older patients had higher rates of adverse events and saw less improvement both in decreases in body mass index (BMI) and self-reported declines in obesity-related health conditions. The 155 older patients—aged 60-76 years—had a 6% mortality after 5 years of follow-up, and 14% had serious morbidities that delayed hospital discharge, such as wound infections and bowel obstructions. Patients reported a 50% reversal in obesity-related comorbidities, and the mean BMI fell from 46 to 31 kg/m² at 1 year, according to senior study author Dr. Michael G. Sarr of the Mayo Clinic.

“Mortality for older patients (0.7%) was significantly lower than that in a previous report about Medicare patients, Dr. Sarr said. That study reported a 30-day mortality of nearly 5% in patients aged 65 and older (JAMA 2005;294:1903-8).” That is not our experience at the Mayo Clinic,” he said. But he added that mortality and morbidity post surgery can be high at centers that perform a low volume of these operations, while high-volume centers carry a much lower risk.

Among 12 adolescents aged 12-18 years, there were no serious adverse events and saw less improvement both in decreases in body mass index (BMI) and self-reported declines in obesity-related health conditions. The 35 older patients—aged 16–76 years—had a 6% mortality after 5 years of follow-up, and 14% had serious morbidities that delayed hospital discharge, such as wound infections and bowel obstructions.

Laparoscopic Nissen Fundoplication Beats Rx

BY DIANA MAHONEY
New England Bureau

Dallas — The steep decline in antireflux surgery since the 1990s may be caused by skepticism following publication of a study suggesting that most patients who undergo surgery eventually resume taking antireflux medication, said Dr. Jonathan F. Finks at the annual meeting of the Society of American Gastrointestinal and Endoscopic Surgeons.

Based on data from the Nationwide Inpatient Sample, the number of patients older than age 18 who underwent antireflux surgery in the United States peaked at 32,907 in the year 2000. By 2003, that rate fell 27% to 23,998 patients.

“The rate of decline was approximately three times greater for patients in the 30- to 50-year-old age range than it was for patients older than 60,” said Dr. Finks of the Mayo Clinic in Minnesota.

The discrepancy may be explained by an increased likelihood of the part on gastroenterologists to reconsider the indications for surgery,” Dr. Fink noted at the meeting.

The bottom line, he said, is that both surgical and medical management of GERD are reasonable options, but the decision on which approach to use should be based on assessment of the risks and benefits for individual patients.

Dr. Finks reported no conflicts of interest with respect to his presentation.
