Heparin Drug Shortage Conservation Strategies
Cassandra D. Benge, PharmD; and Abigail T. Burka, PharmD

Heparin is the anticoagulant of choice when a rapid anticoagulant is indicated: Onset of action is immediate when administered IV as a bolus. The major anticoagulant effect of heparin is mediated by heparin/antithrombin (AT) interaction. Heparin/AT inactivates factor IIa (thrombin) and factors Xa, IXa, Xla, and XIIa. Heparin is approved for multiple indications, such as venous thromboembolism (VTE) treatment and prophylaxis of medical and surgical patients; stroke prevention in atrial fibrillation (AF); acute coronary syndrome (ACS); vascular and cardiac surgeries; and various interventional procedures (eg, diagnostic angiography and percutaneous coronary intervention [PCI]). It also is used as an anticoagulant in blood transfusions, extracorporeal circulation, and for maintaining patency of central vascular access devices (CVADs).

About 60% of the crude heparin used to manufacture heparin in the US originates in China, derived from porcine mucosa. African swine fever, a contagious virus with no cure, has eliminated about 25% to 35% of China’s pig population, or about 150 million pigs. In July 2019, members of the US House of Representatives Committee on Energy and Commerce sent a letter to the US Food and Drug Administration asking for details on the potential impact of African swine fever on the supply of heparin.

The US Department of Veterans Affairs (VA) health care system is currently experiencing a shortage of heparin vials and syringes. It is unclear when resolution of this shortage will occur as it could resolve within several weeks or as late as January 2020. Although vials and syringes are the current products that are affected, it is possible the shortage may eventually include IV heparin bags as well.

Since the foremost objective of VA health care providers is to provide timely access to medications for veterans, strategies to conserve unfractionated heparin (UFH) must be used since it is a first-line therapy where few evidence-based alternatives exist. Conservation strategies may include drug rationing, therapeutic substitution, and compounding of needed products using the limited stock available in the pharmacy.

In shortage situations, the VA-Pharmacy Benefits Management (PBM) defers decisions regarding drug preservation, processes to shift to viable alternatives, and the best practice for safe transitions to local facilities and their subject matter experts. At the VA Tennessee Valley Healthcare System, a 1A, tertiary, dual campus health care system, a pharmacy task force has formed to track drug shortages impacting the facility’s efficiencies and budgets. This group communicates with the Pharmacy and Therapeutics committee about potential risks to patient care and develops shortage briefs (following an SBAR [situation, background, assessment, recommendation] design) generally authored and championed by at least 1 clinical pharmacy specialist and supervising physicians who are field experts. Prior to dissemination, the SBAR undergoes a rapid peer-review process.

To date, VA PBM has not issued specific guidance on how pharmacists should proceed in case of a shortage. However, we recommend strategies that may be considered for implementation during a potential UFH shortage. For example, pharmacists can use therapeutic alternatives for which best available evidence suggests no disadvantage. The Table lists alternative agents according to indication and patient-specific considerations that may preclude use. Existing UFH products may also be used for drug compounding (eg, use current stock to provide an indicated aliquot) to meet the need of prioritized patients. In addition, we suggest prioritizing current UFH/heparinized saline for...

Abbreviations: ACS, acute coronary syndrome; ACT, activated clotting time; BL, baseline; BMI, body mass index; CCL, cardiac catheterization laboratory; CI, continuous infusion; CrCl, creatinine clearance; CVAD, central vascular access device; HIT, heparin-induced thrombocytopenia; HITTS, heparin-induced thrombocytopenia with thrombosis syndrome; ICU, intensive care unit; IHD; ischemic heart disease (stable and unstable disease); IMPROVE, International Medical Prevention Registry on Venous Thromboembolism; IV, intravenous; LHC, left heart cardiac catheterization; NSTE ACS, Non-ST elevation myocardial infarction/acute coronary syndrome; PCI, percutaneous coronary intervention (eg, stenting); PICC, peripherally inserted central catheter; RAO, radial artery occlusion; RCA, regional citrate anticoagulation; SC, subcutaneous; SQH, subcutaneous heparin; STEMI, ST elevation myocardial infarction; tPA, tissue plasminogen activator; VTE, venous thromboembolism; WT, weight.

*Hip arthroplasty or fracture.*

use for the following groups of patients:
- Emergent/urgent cardiac surgery,
- Hemodialysis patients for which the low-molecular-weight heparin (LMWH) dalteparin is deemed inappropriate or the patient is not monitored in the intensive care unit for regional citrate administration;
- VTE prophylaxis for patients with epidurals or chest tubes for which urgent invasive management may occur, recent cardiac or neurosurgery, or for patients with a creatinine clearance < 15 mL/min or receiving hemodialysis;
- Vascular surgery (eg, limb ischemia) and interventions (eg, carotid stenting, endarterectomy);
- Mesenteric ischemia (venous thrombosis) with a potential to proceed to laparotomy;
- Critically ill patients with arterial lines.
for which normal saline is deemed inap-
appropriate for line flushing; Electrophysiology procedures (eg, AF ab-
alation) and Contraindication to use of a long-acting altern-
tive listed in the table or a medical ne-
necessity exists for using a rapidly reversible agent. Examples for this category include but are not limited to recent gastrointes-
tinal bleeding, central nervous system le-
sion, and select neurologic diagnoses (eg, cerebral venous sinus thrombosis with hemorrhage, thrombus in vertebral basilar system or anterior circulation, intraparen-
chymal hemorrhage plus mechanical valve, medium to large cardioembolic stroke with intracardiac thrombus).

**CONCLUSION**

The UfH drug shortage represents a signifi-
cant threat to public health and is a major challenge for US health care systems, includ-
ing the Veterans Health Administration. Over-
reliance on a predominant source of crude

</table>
heparin has affected multiple UfH manufacturers and products. Current alternatives to UfH include low-molecular-weight heparins, IV direct thrombin inhibitors, and SC fondaparinux, with selection supported by guidelines or evolving literature. However, the shortage has the potential to expand to other injectables, such as dalteparin and enoxaparin, and severely limit care for veterans. It is vital that clinicians rapidly address the current shortage by creating a plan to develop efficient and equitable access to UfH, continue to assess supply and update stakeholders, and select evidence-based alternatives while maintaining focus on efficacy and safety.

Acknowledgments
The authors thank Ashley Yost, PharmD, for her coordination of the multidisciplinary task force assigned to efficiently manage the heparin drug shortage. This material is the result of work supported with resources and the use of facilities at the VA Tennessee Valley Healthcare System in Nashville, Tennessee.
