Abemaciclib becomes first CDK inhibitor to clinch single-agent approval for breast cancer

The fall 2017 approval by the US Food and Drug Administration (FDA) of abemaciclib made it the third cyclin-dependent kinase (CDK) inhibitor approved for the treatment of hormone receptor (HR)-positive breast cancer, and the first to receive an approved indication as monotherapy in that setting. Abemaciclib is a small–molecule inhibitor of the CDK4 and CDK6 proteins, which are key gatekeepers of the cell cycle and frequently dysregulated in HR-positive breast cancer. On the basis of the randomized, placebo-controlled, multicenter phase 3 MONARCH-2 trial, it was approved in combination with fulvestrant for the treatment of women with HR-positive, HER2-negative advanced or metastatic breast cancer who had progressed during endocrine therapy.1

A total of 669 women aged 18 years and older, with any menopausal status, an Eastern Cooperative Oncology Group (ECOG) Performance Status of 0 or 1, measurable disease per Response Evaluation Criteria in Solid Tumors (RECIST, version 1.1) or nonmeasurable bone-only disease, were enrolled. Patients had progressed during neoadjuvant or adjuvant endocrine therapy, within 12 months of adjuvant endocrine therapy, or during frontline endocrine treatment for metastatic disease.

Those who had received more than 1 endocrine therapy or any prior chemotherapy for metastatic breast cancer or prior treatment with everolimus or CDK4/6 inhibitors, as well as those with the presence of visceral crisis or evidence or history of central nervous system (CNS) metastases, were excluded from the study.

Patients were randomized 2:1 to receive 150 mg abemaciclib or placebo, both in combination with 500 mg fulvestrant. The initial dose of abemaciclib was 200 mg, but this was amended to 150 mg because of diarrhea-related toxicity concerns.

The primary endpoint was progression-free survival (PFS). Median PFS for abemaciclib was 16.4 months and for placebo, 9.3 months (HR, 0.553; P < .0000001), an effective 45% reduction in risk for progression or death with the combination. ORR among patients with measurable disease was 48.1% and 21.3%, respectively, including a CRR of 3.5% with abemaciclib. The median DoR was not yet reached in the study group (25.6 months for placebo). Overall survival data were not yet mature.

The most common adverse events experienced with abemaciclib–fulvestrant were neutropenia (23.6%) and diarrhea (13.4%). Grade 4 neutropenia was higher in the study arm compared with placebo (2.9% vs 0.4%), with 3 deaths with the combination linked to treatment-related AEs. Abemaciclib carries warnings and precautions relating to diarrhea, neutropenia, hepatotoxicity, VTE, and embryofetal toxicity. Pregnant women should be advised of the potential risk to a fetus, and those of reproductive potential should be counselled on the importance of using effective contraception during treatment and for at least 3 weeks after the last dose.

— Jame Abraham, MD, FACP (abrahaj5@ccf.org)

Objective response rate in the 2 groups among patients with measurable disease was 48.1% and 21.3%, respectively, which included a complete response rate of 3.5% in the abemaciclib arm. The median duration of response was not yet reached in the study group, compared with 25.6 months for placebo. Overall survival data were not yet mature.

The agency also approved abemaciclib as monotherapy for women and men with HR-positive, HER2-negative advanced or metastatic breast cancer with disease progression following endocrine therapy and prior chemotherapy setting. Exclusion criteria included prior receipt of a CDK inhibitor, major surgery within 14 days of the start of the study, and CNS metastases.

Tumor assessments were performed by CT or MRI according to RECIST-1.1 within the 4 weeks prior to the first dose of study drug and then subsequently at every other cycle. Responses were confirmed at least 4 weeks after the initial observation. The overall response rate was 19.7%, made up completely of partial responses. Median duration of response was 8.6 months, median PFS was 6 months and median OS was 17.7 months.

**Adverse events**

The most common adverse events experienced with the...
combination of abemaciclib and fulvestrant were neutropenia (23.6%) and diarrhea (13.4%). The rate of grade 4 neutropenia was higher in the combination arm (2.9% vs 0.4%) and there were 3 deaths with the combination that were linked to treatment-related AEs. In the monotherapy trial, abemaciclib treatment most commonly caused diarrhea (90.2%), fatigue (65.2%), nausea (64.4%), decreased appetite (45.5%), and abdominal pain (38.6%). Grade 3 diarrhea and fatigue occurred in 19.7% and 12.9% of patients, respectively. Serious AEs occurred in 24.2% of patients and AEs led to treatment discontinuation in 7.6% of patients.

**Warnings and precautions**
Abemaciclib is marketed as Verzenio by Eli Lilly and Company. Warnings and precautions relating to diarrhea, neutropenia, hepatotoxicity, venous thromboembolism (VTE), and embryofetal toxicity are detailed in the prescribing information. In the event of diarrhea, patients should be treated with antidiarrheal therapy and should increase oral fluids and notify their health care provider. Treatment should be interrupted for grade 3 or 4 diarrhea and then resumed at a lower dose upon return to grade 1.

To guard against neutropenia, complete blood counts should be performed prior to starting therapy, every 2 weeks for the first 2 months, monthly for the subsequent 2 months, and then as clinically indicated. Treatment should be interrupted or delayed or the dose reduced for grade 3 or 4 neutropenia and patients should report episodes of fever.

Liver function tests should be performed before starting abemaciclib, every 2 weeks for the first 2 months, monthly for the next 2 months, and then as clinically indicated. For patients who develop persistent or recurrent grade 2, 3 or 4 hepatic transaminase elevation, dose interruption, reduction, discontinuation, or delay should be considered. Patients should be monitored for signs and symptoms of VTE and pulmonary embolism, and treated appropriately. Pregnant women should be advised of the potential risk to a fetus, and those of reproductive potential should be counselled on the importance of using effective contraception during treatment and for at least 3 weeks after the last dose.
